### Water Chemistry and Pretreatment: Calcium Phosphate Scale Prevention

#### Calcium Phosphate Scale Prevention

Calcium phosphate fouling was not common until reverse osmosis technology was widely applied to municipal wastewater. Due to water shortages, municipal waste water recycle or reuse has become one a major application area of reverse osmosis. Along with this new application, preventive actions for calcium phosphate scaling are needed.

Phosphorus is a common element in nature and is widely distributed in many minerals. In natural water and waste water streams, phosphorus compounds exist in the following forms:

[/18/](#)

- Particulate phosphate
- Orthophosphate ( $\text{PO}_4^{3-}$ ): Orthophosphates may be present as  $\text{H}_3\text{PO}_4$ ,  $\text{H}_2\text{PO}_4^-$ ,  $\text{HPO}_4^{2-}$ , and  $\text{PO}_4^{3-}$  depending on pH.  $\text{H}_2\text{PO}_4^-$  and  $\text{HPO}_4^{2-}$  are the prevailing species in neutral waste water.
- Polyphosphates: Important components in textile washing powders and other detergents. Depending on the product, they may contain 2–7 P atoms.
- Organic phosphorus: Phosphorus is an essential element for living organisms.
- The most common mineral form of phosphorus is apatite, which is a calcium phosphate with variable amounts of  $\text{OH}^-$ ,  $\text{Cl}^-$ , and  $\text{F}^-$  (hydroxy-, chloro-, or fluoroapatite). Some other phosphate minerals contain aluminum and/or iron. Because of their low solubility, the following phosphate compounds can be considered as causes of phosphate scaling in an RO/NF operation (see Table 2.8).

**Table 2.8 Low solubility phosphate compounds**

Compound	Formula	pK <sub>sp</sub>
Brushite	$\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$	6.68
Calcium phosphate	$\text{Ca}_3(\text{PO}_4)_2$	28.9
Octacalcium phosphate	$\text{Ca}_8\text{H}(\text{PO}_4)_6 \cdot 3\text{H}_2\text{O}$	46.9
Hydroxyapatite	$\text{Ca}_5(\text{PO}_4)_3\text{OH}$	57.74
Fluoroapatite	$\text{Ca}_5(\text{PO}_4)_3\text{F}$	60
Magnesium ammonium phosphate	$\text{MgNH}_4\text{PO}_4$	12.6
Aluminum phosphate	$\text{AlPO}_4$	20
Iron phosphate	$\text{FePO}_4$	15

Calcium phosphate and apatites are less soluble in neutral and alkaline conditions and dissolve in acid [/18/](#). Aluminum and iron phosphates, however, are less soluble at moderately acidic conditions. Thus it is important to remove aluminum and iron in a pretreatment step as well. Because of the complexity of phosphate chemistry, it is not easy to predict a threshold level of phosphate scaling. The calcium phosphate stability index (SI), however, was proposed by Kubo et al [/19/](#). The calcium phosphate stability index is determined by the levels of calcium and phosphate present, pH, and temperature. A negative SI signifies a low potential for calcium phosphate scaling; a positive value indicates the potential for calcium phosphate scaling. SI is determined by the following equation:

$$SI = pH_a - pH_c$$

where:

$pH_a$  = actual pH of a feed water

$pH_c$  = critical pH calculated by the following experimental equation:

$$pH_c = \frac{11.755 - \log(\text{CaH}) - \log(\text{PO}_4) - 2\log t}{0.65}$$

where :

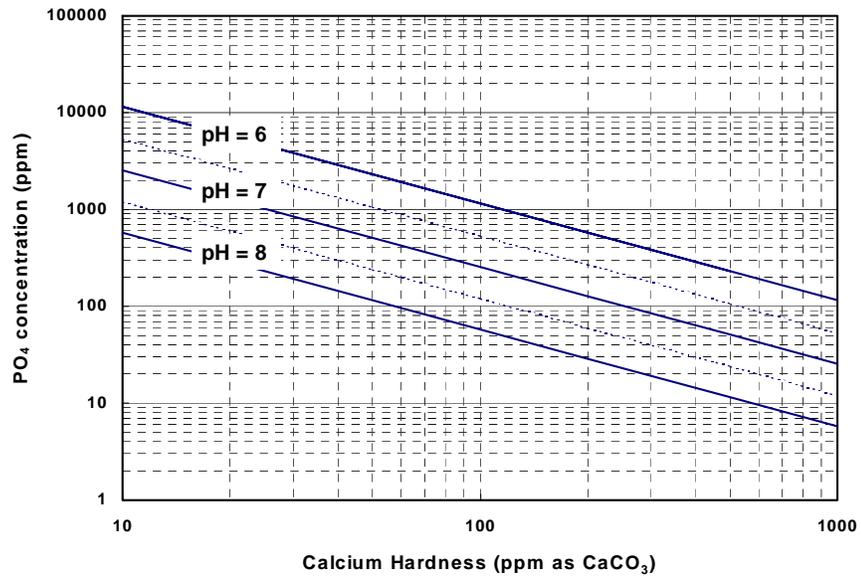

CaH = Calcium hardness as ppm  $\text{CaCO}_3$

$\text{PO}_4$  = Phosphate concentration as ppm  $\text{PO}_4$

$t$  = Temperature as  $^\circ\text{C}$

Figure 2.12 shows the effect of critical phosphate concentrations of  $\text{Ca}_3(\text{PO}_4)_2$  scaling on feed calcium hardness and pH based on the equation.

Figure 2.12 Critical phosphate concentration under various pH at 25°C

To minimize the risk of phosphate scaling, it is important to reduce not only orthophosphate, but also calcium, fluoride, and aluminum concentration. A low feed pH helps to control phosphate scaling. Appropriate commercial antiscalants good for phosphate scaling are also available.

Phosphate scaled membranes are best cleaned at low pH - see [Cleaning Chemicals \(Section 6.8\)](#).

#### FILMTEC™ Membranes

For more information about FILMTEC membranes, call the Dow Liquid Separations business:
